Chapter 1

Schedule Properties and Argumentation

Schedule properties such as efficiency are modelled using frameworks to explain the satisfaction of properties. In particular, the definitions of efficiency and fixed decision frameworks extend from the definition of the feasibility framework. This is generalised to reason about arbitrary number of properties, using a commonly-extended framework. Using this extended reasoning, we apply argumentation to a variant interval scheduling to illustrate extensions of argumentation.

1.1 Extensions

We use stability over other notions of good extensions to accurately model schedule constraints.

1.2 Frameworks

In order to reason about arbitrary number of properties, we inductively build the expressible properties over a commonly-extended framework, denoted by \leadsto_0 . A property P is modelled by the framework \leadsto_P . To be correct, we must preserve the stability of some extension E on $\langle Args, \leadsto_0 \cup \leadsto_P \rangle$ if E is also stable on $\langle Args, \leadsto_0 \rangle$ and P(S) is true. Let $\leadsto_1 \subseteq Args^2$ and $\leadsto_2 \subseteq Args^2$ be arbitrary frameworks.

Definition 1. A framework \rightsquigarrow stability-models a schedule property P iff for all extensions E and corresponding schedules S, E is stable on $\langle Args, \rightsquigarrow \rangle \Leftrightarrow P(S)$

Definition 2. A framework \leadsto conflict-models a schedule property P iff for all extensions E and corresponding schedules S, E is conflict-free on $\langle Args, \leadsto \rangle \Leftrightarrow P(S)$

The definitions of stability-models and conflict-models allows construction of concise proofs by using lemmas the partially prove correctness.

Proposition 1. \leadsto_F stability-models feasibility.

Proposition 2. \leadsto_S stability-models feasibility and efficiency.

Proposition 3. \leadsto_D stability-models feasibility and satisfaction of fixed decisions.

Definition 3. A schedule property P is stability-modellable iff there exists a framework that stability-models P.

Lemma 1. E is conflict-free on $\langle Args, \leadsto_1 \rangle$ and on $\langle Args, \leadsto_2 \rangle$ iff E is conflict-free on $\langle Args, \leadsto_1 \cup \leadsto_2 \rangle$.

Proof. To prove the forward implication, assume E is conflict-free on $\langle Args, \leadsto_1 \rangle$ and on $\langle Args, \leadsto_2 \rangle$. To aim for a contradiction, assume E is not conflict-free on $\langle Args, \leadsto_1 \cup \leadsto_2 \rangle$. Then there exists $e_1, e_2 \in E$ such that $e_1(\leadsto_1 \cup \leadsto_2)e_2$. Then $e_1 \leadsto_1 e_2$ or $e_1 \leadsto_2 e_2$. Both cases lead to a contradiction, so E is conflict-free on $\langle Args, \leadsto_1 \cup \leadsto_2 \rangle$.

To prove the backward implication, assume E is conflict-free on $\langle Args, \leadsto_1 \cup \leadsto_2 \rangle$. To aim for a contradiction, assume E is not conflict-free on $\langle Args, \leadsto_1 \rangle$. Then there exists $e_1, e_2 \in E$ such that $e_1 \leadsto_1 e_2$. Then $e_1(\leadsto_1 \cup \leadsto_2)e_2$, which contradicts the most recent assumption. Therefore, E is conflict-free on $\langle Args, \leadsto_1 \rangle$, and also conflict-free on $\langle Args, \leadsto_2 \rangle$ by similar argument. \square

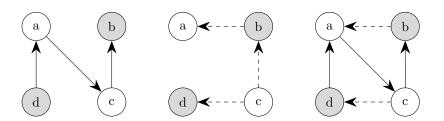

Figure 1.1: Lemma 1 states that given a conflict-free extension over two attack sets on the same arguments, the extension is conflict-free on the merged framework. The figure illustrates this by merging the left and middle frameworks to produce the right framework.

Lemma 2. If E is stable on $\langle Args, \leadsto_1 \rangle$ and E is conflict-free on $\langle Args, \leadsto_2 \rangle$, then E is stable on $\langle Args, \leadsto_1 \cup \leadsto_2 \rangle$.

Proof. Assume E is stable on \leadsto_1 and E is conflict-free on \leadsto_2 . By definition of stability, $\forall a \in Args \setminus E \ \exists e \in E \ e \leadsto_1 a$. Then $\forall a \in Args \setminus E \ \exists e \in E \ e (\leadsto_1 \cup \leadsto_2)a$. So every argument not in E is attacked by some argument in E. E is conflict-free on \leadsto_1 because E is stable on \leadsto_1 . Since E is conflict-free on \leadsto_1 and on \leadsto_2 , we use Lemma 1 to show that E is also conflict-free on $(\leadsto_1 \cup \leadsto_2)$. Therefore E is stable on $\langle Args, \leadsto_1 \cup \leadsto_2 \rangle$.

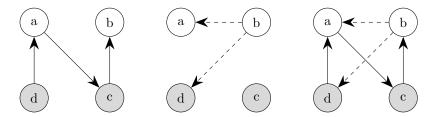

Figure 1.2: Lemma 2 allows stable extensions of attacks to grow with conflict-free attacks. Note that the right, merged framework is stable while the left, base framework is stable.

Lemma 3. If E is stable on $\langle Args, \leadsto_1 \cup \leadsto_2 \rangle$, then E is conflict-free on $\langle Args, \leadsto_1 \rangle$.

Proof. Assume E is stable on $\langle Args, \leadsto_1 \cup \leadsto_2 \rangle$. By definition of stability, E is conflict-free on $\langle Args, \leadsto_1 \cup \leadsto_2 \rangle$. By Lemma 1, E is conflict-free on $\langle Args, \leadsto_1 \rangle$.

Figure 1.3: Lemma 3 states that given a stable extension, removing attacks preserves the extension's conflict-freeness, as shown from left to right.

Lemma 4. If E is stable on $\langle Args, \leadsto_1 \cup \leadsto_2 \rangle$ and $\forall a \in Args \setminus E \ (\exists e \in E \ e \leadsto_2 a) \implies (\exists e \in E \ e \leadsto_1 a)$, then E is stable on $\langle Args, \leadsto_1 \rangle$.

Proof.

$$E \text{ is stable on } \langle Args, \leadsto_1 \cup \leadsto_2 \rangle$$

$$\wedge \forall a \in Args \setminus E \ (\exists e \in E \ e \leadsto_2 a) \implies (\exists e \in E \ e \leadsto_1 a)$$

$$\implies E \text{ is conflict-free on } \langle Args, \leadsto_1 \cup \leadsto_2 \rangle$$

$$\wedge \forall a \in Args \setminus E \ \exists e \in E \ e (\leadsto_1 \cup \leadsto_2)$$

$$\wedge \forall a \in Args \setminus E \ (\exists e \in E \ e \leadsto_2 a) \implies (\exists e \in E \ e \leadsto_1 a)$$

$$\implies E \text{ is conflict-free on } \langle Args, \leadsto_1 \rangle$$

$$\wedge \forall a \in Args \setminus E \ \exists e \in E \ (e \leadsto_1 a \lor e \leadsto_2 a)$$

$$\wedge \forall a \in Args \setminus E \ (\exists e \in E \ e \leadsto_2 a) \implies (\exists e \in E \ e \leadsto_1 a)$$

$$\implies E \text{ is conflict-free on } \langle Args, \leadsto_1 \rangle$$

$$\wedge \forall a \in Args \setminus E \ ((\exists e \in E \ e \leadsto_1 a) \lor (\exists e \in E \ e \leadsto_2 a))$$

$$\wedge \forall a \in Args \setminus E \ ((\exists e \in E \ e \leadsto_2 a) \implies (\exists e \in E \ e \leadsto_1 a)$$

$$\implies E \text{ is conflict-free on } \langle Args, \leadsto_1 \rangle$$

$$\wedge \forall a \in Args \setminus E \ ((\exists e \in E \ e \leadsto_1 a) \lor (\exists e \in E \ e \leadsto_1 a))$$

$$\implies E \text{ is conflict-free on } \langle Args, \leadsto_1 \rangle$$

$$\wedge \forall a \in Args \setminus E \ (\exists e \in E \ e \leadsto_1 a)$$

$$\implies E \text{ is conflict-free on } \langle Args, \leadsto_1 \rangle$$

$$\wedge \forall a \in Args \setminus E \ \exists e \in E \ e \leadsto_1 a$$

$$\implies E \text{ is stable on } \langle Args, \leadsto_1 \rangle$$

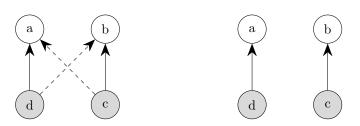

Figure 1.4: Lemma 4 states that given a stable extension, removing attacks on multi-attacked arguments preserves the extension's stability, as shown from left to right.

Theorem 1 (Union of modelling frameworks). Let $P_0, ..., P_K$ be schedule properties with K properties. Let $P_{\llbracket i,j \rrbracket}$ be an aggregate schedule property where for all schedules $S, P_{\llbracket i,j \rrbracket}(S) \Leftrightarrow \forall k \in \llbracket i,j \rrbracket \ P_k(S)$.

If \leadsto_0 stability-models P_0 , and $\forall k \in \llbracket 1, K \rrbracket \implies_k$ conflict-models P_k , and for all extensions E, $\forall a \in Args \setminus E \ \forall k \in \llbracket 1, K \rrbracket \ \big((\exists e \in E \ e \leadsto_k a) \implies (\exists e \in E \ e \leadsto_0 a) \big)$, then $\left(\bigcup_{k=0}^K \leadsto_k \right)$ stability-models $P_{\llbracket 0, K \rrbracket}$.

Proof. Take arbitrary $K \in \mathbb{N}$. To prove forward implication:

1.
$$\leadsto_0$$
 stability-models P_0 given
2. $\forall k \in [1, K] \leadsto_k$ conflict-models P_k

- 3. $\forall a \in Args \setminus E \ \forall k \in \llbracket 1, K \rrbracket \ \left((\exists e \in E \ e \leadsto_k a) \implies (\exists e \in E \ e \leadsto_0 a) \right)$ given
- 4. E is stable on $\langle Args, \bigcup_{k=0}^K \leadsto_k \rangle$ assumption

5.
$$\forall a \in Arg \setminus E \left(\left(\exists e \in E \ e \left(\bigcup_{k=0}^K \leadsto_k \right) a \right) \implies (\exists e \in E \ e \leadsto_0 a) \right)$$

- 6. E is stable on $\langle Args, \leadsto_0 \rangle$ lemma 4, 4, 5
- 7. $P_0(S)$ 1, 6
- 8. Take arbitrary $k \in [1, K]$
 - 9. E is conflict-free on $\langle Args, \leadsto_k \rangle$ lemma 3, 4
 - 10. $P_k(S)$ 2, 9
- 11. $\forall k \in [1, K] P_k(S)$ 8, 10
- 12. $P_{[0,K]}(S)$ 7, 11

To prove backward implication:

- 1. \leadsto_0 stability-models P_0 given
- 2. $\forall k \in [1, K] \sim_k \text{conflict-models } P_k$ given
- 3. $P_{\llbracket 0,K\rrbracket}(S)$ assumption
- 4. $P_0(S)$
- 5. E is stable on $\langle Args, \leadsto_0 \rangle$ 1, 4
- 6. Recursively over $k \in [1, K]$
 - 7. $P_k(S)$ 3
 - 8. E is conflict-free on $\langle Arg, \leadsto_k \rangle$ 2, 7
 - 9. E is stable on $\langle Arg, \bigcup_{k'=0}^k \leadsto_{k'} \rangle$ lemma 2, 5, 8
- 10. E is stable on $\langle Arg, \bigcup_{k=0}^K \leadsto_k \rangle$ 6, 9

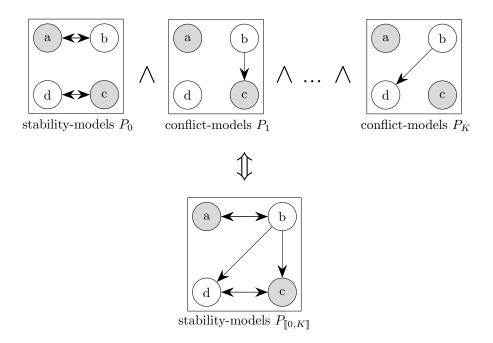

Figure 1.5: Theorem 1 allows manipulation of an aggregate property, $P_{\llbracket 0,K \rrbracket}$ from carefully overlaying frameworks, while preserving stability. This theorem is a key statement in framing argumentation semantics for arbitrary scheduling problems.

Theorem 1 cannot be applied to \leadsto_S or \leadsto_D because they remove attacks from the \leadsto_F . The theorem does not capture removal of attacks from a commonly-extendable framework because there is ambiguity between the order of removal and insertion of attacks. Formally, $(\leadsto \cup \leadsto^+) \setminus \leadsto^- \neq (\leadsto \setminus \leadsto^-) \cup \leadsto^+$ for arbitrary frameworks $\leadsto, \leadsto^-, \leadsto^+$.

1.3 Interval Scheduling

Makespan schedules are extended to discrete time-indexed interval scheduling. Let T be the exclusive upper-bound of indexed time where $\mathcal{T} = \{0, ..., T-1\}$. The assignment matrix $\mathbf{x} \in \mathcal{M} \times \mathcal{J} \times \mathcal{T}$ is extended such that $x_{i,j,t} = 1$ iff job j is starts work on machine i at time t. Each machine job pair $\langle i,j \rangle$ has a start time $s_{i,j} \in \mathcal{T}^{mn}$ and finish time $f_{i,j} \in \{0, ..., T\}^{mn}$, where j must be completed within the $[s_{i,j}, f_{i,j})$ interval. The objective is to minimise the total completion time.

$$\min_{\mathbf{x}} \ C_{\max} \ \text{subject to:}$$

$$\forall i \in \mathcal{M} \ \forall j \in \mathcal{J} \ \forall t \in \mathcal{T} \ C_{\max} \geq x_{i,j,t}(t+p_j)$$

$$\forall j \in \mathcal{J} \ \sum_{i \in \mathcal{M}} \sum_{t \in \mathcal{T}} x_{i,j,t} = 1 \qquad \alpha$$

$$\forall i \in \mathcal{M} \ \forall t \in \mathcal{T} \ \sum_{j \in \mathcal{J}} \sum_{t' = \max\{t-p_j+1,0\}}^t x_{i,j,t'} \leq 1 \quad \beta$$

$$\forall i \in \mathcal{M} \ \forall j \in \mathcal{J} \ \forall t \in \{0,...,s_{i,j}-1\} \ x_{i,j,t} = 0 \qquad \qquad \gamma$$

$$\forall i \in \mathcal{M} \ \forall j \in \mathcal{J} \ \forall t \in \{f_{i,j}-p_j+1,...,T-1\} \ x_{i,j,t} = 0 \qquad \qquad \delta$$

$$\forall \langle i,j,t\rangle \in D^- \ x_{i,j,t} = 0 \qquad \qquad \varepsilon$$

$$\forall \langle i',j,t'\rangle \in D^+ \ \forall i \in \mathcal{M} \setminus \{i'\} \ \forall t \in \mathcal{T} \ x_{i,j,t} = 0$$

$$\forall \langle i,j,t'\rangle \in D^+ \ \forall t \in \mathcal{T}$$

$$t \leq t'-p_j \lor t \geq t'+p_j \implies x_{i,j,t} = 0$$

 α models feasibility, that all jobs must be allocated. β models that machines cannot process multiple jobs at the same time. γ and δ models the restriction of start and end times respectively. ε and ζ models negative and positive fixed decisions respectively. Equivalently, ζ can be modelled by $\forall \langle i,j,t' \rangle \in D^+ \exists t \in \mathcal{T} \ x_{i,j,t} = 1$. ζ is defined as such to simplify the proof that the union of these properties is modelable. η models enforces that j is working on i at t, but does not specify the when j starts. Note that γ, δ, ζ and η can be modelled using ε . We use overlapping constraints to give better explanations. For argumentation, let $Args = \mathcal{M} \times \mathcal{J} \times \mathcal{T}$.

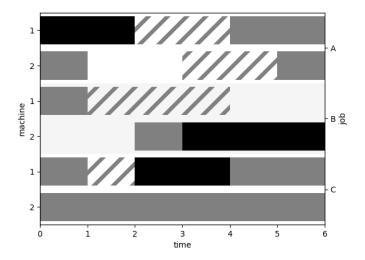

Figure 1.6: An interval schedule, where black areas are assignments and the grey areas show invalid slots because of negative fixed decisions or other job assignees.

Definition 4. Let \leadsto_{α} be the base-feasibility framework such that $\langle i, j, t \rangle \leadsto_{\alpha} \langle i', j', t' \rangle \Leftrightarrow i \neq i' \land j = j' \land t \neq t'$

Lemma 5. \leadsto_{α} stability-models α .

Proof. To prove forward implication: E is stable on $\langle Args, \iff \alpha \rangle$. Take arbitrary $j \in \mathcal{J}$. To aim to contradict, assume $\sum_{i \in \mathcal{M}} \sum_{t \in \mathcal{T}} x_{i,j,t} > 1$. Then $\exists \langle i, j, t \rangle, \langle i', j, t' \rangle \in E$ where $x_{i,j,t} = 1$ and $x_{i',j,t'} = 1$ such that $i \neq i'$ or $t \neq t'$. By definition of \leadsto_{α} , $\langle i, j, t \rangle \leadsto_{\alpha} \langle i', j, t' \rangle$. Hence E is not conflict-free, then E is not stable. By contradiction, $\sum_{i \in \mathcal{M}} \sum_{t \in \mathcal{T}} x_{i,j,t} \leq 1$. To aim to contradict, assume $\sum_{i \in \mathcal{M}} \sum_{t \in \mathcal{T}} x_{i,j,t} = 0$. Then $\forall i \in \mathcal{M} \ \forall t \in \mathcal{T} \ \langle i, j, t \rangle \notin E$. Then E is not stable. By contradiction, $\sum_{i \in \mathcal{M}} \sum_{t \in \mathcal{T}} x_{i,j,t} > 0$. Therefore α holds.

To prove backward implication: From α , there is exactly one $i \in \mathcal{M}$ and $t \in \mathcal{T}$ such that $x_{i,j,t} = 1$. So E is conflict free. Also, for all j, $\langle i, j, t \rangle \in E$ attacks every other $\langle i, t \rangle$, so E is stable.

Definition 5. Let \leadsto_{β} be the sequential-feasibility framework such that $\langle i, j, t \rangle \leadsto_{\beta} \langle i', j', t' \rangle \Leftrightarrow i = i' \land (t' \le t \le t' + p_j \lor t \le t' < t + p_j).$

Lemma 6. \leadsto_{β} conflict-models β .

Proof. To prove forward implication: Take arbitrary $i \in \mathcal{M}$, $t \in \mathcal{T}$. To aim for a contradiction, assume $\sum_{j \in \mathcal{J}} \sum_{t' \in \max\{t-p_j+1,0\}} x_{i,j,t'} \geq 2$. Then there exists some $j_1, j_2 \in \mathcal{J}$ and some $t_1, t_2 \in \mathcal{T}$ such that $0 \leq t_1, t_2 \leq t$ and $x_{i,j_2,t_2} + x_{i,j_2,t_2} = 2$. Then $\langle i, j_1, t_1 \rangle \in E$ and $\langle i, j_2, t_2 \rangle \in E$. By conduction of β , then either $t_1 \leq t_2 \leq t_1 + p_1$ or $t_2 \leq t_1 \leq t_2 + p_2$. By definition of \leadsto_{β} ,

 $\langle i, j_1, t_1 \rangle \leadsto_{\beta} \langle i, j_2, t_2 \rangle$. But this contradicts that E is conflict-free. Therefore β holds.

To prove backward implication: Assume β holds. Take arbitrary $i \in \mathcal{M}$, $t \in \mathcal{T}$. Then there does not exists overlapping jobs j_1 and j_2 such that $x_{i,j_1,t_1}+x_{i,j_2,t_2}=2$. Then $\langle i,j_1,t_1\rangle \notin E$ and $\langle i,j_2,t_2\rangle \notin E$. Therefore, E is conflict-free.

Definition 6. Let \leadsto_{γ} be a start-feasibility framework such that $\leadsto_{\gamma} = \{ \langle \langle i, j, t \rangle, \langle i, j, t \rangle \rangle \mid i \in \mathcal{M}, j \in \mathcal{J}, 0 \leq t < s_{i,j} \}.$

Definition 7. Let \leadsto_{δ} be a finish-feasibility framework such that $\leadsto_{\delta} = \{ \langle \langle i, j, t \rangle, \langle i, j, t \rangle \rangle \mid i \in \mathcal{M}, j \in \mathcal{J}, f_{i,j} - p_j < t < T \}.$

Definition 8. Let \leadsto_{ε} be the negative fixed decision feasibility framework such that

 $\leadsto_{\varepsilon} = \{ \langle \langle i, j, t \rangle, \langle i, j, t \rangle \rangle \mid \langle i, j \rangle \in D^{-}, t \in \mathcal{T} \}.$

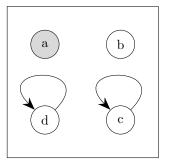

Definition 9. Let \leadsto_{ζ} be a positive fixed decision feasibility framework such that $\leadsto_{\varepsilon} = \{ \langle \langle i, j, t \rangle, \langle i, j, t \rangle \rangle \mid i \in \mathcal{M}, \langle i', j, t' \rangle \in D^+, i \neq i', t \in \mathcal{T} \}.$

Definition 10. Let \leadsto_{η} be a positive fixed decision feasibility framework such that $\leadsto_{\varepsilon} = \{\langle \langle i, j, t \rangle, \langle i, j, t \rangle \rangle \mid \langle i, j, t' \rangle \in D^+, t \in \mathcal{T}, t \leq t' - p_j \vee t \geq t' + p_j \}.$

Lemma 7. Let $A \subseteq Args$ be the set of arbitrary negative fixed decisions. A schedule S satisfies these decisions if property P_A holds. Formally $P_A \iff \forall a \in A \ x_a = 0$. If \leadsto_A is defined by $\leadsto_A = \{\langle a, a \rangle \mid a \in A\}$, then \leadsto_A conflict-models P_A .

Proof. To prove forward implication: Assume E is conflict free on $\langle Args, \leadsto_{\mathcal{A}} \rangle$. Take arbitrary $a \in \mathcal{A}$. To aim for a contradiction, assume $x_a = 1$. Then $a \in E$. By definition of $\leadsto_{\mathcal{A}}$, $a \leadsto_{\mathcal{A}} a$. But this contradicts E is conflict-free so $x_a = 0$. Therefore $P_{\mathcal{A}}(S)$ holds.

To prove backward implication: Assume $P_{\mathcal{A}}(S)$ holds. Take arbitrary $a \in \mathcal{A}$. To aim for a contradiction, assume $a \leadsto_{\mathcal{A}} a$. Then $a \in E$, so $x_a = 1$. This contradicts $P_{\mathcal{A}}(S)$, so E is conflict-free.

conflict-models $P_{\mathcal{A}}$ with $\mathcal{A} = \{c, d\}$

Figure 1.7: Self-attacking arguments cannot be members of stable extensions. Lemma 7 exploits self-attacks to conflict-model negative fixed decisions.

Lemma 8. For all extensions E, $\forall a \in Args \setminus E \ \forall \lambda \in \{\beta, \gamma, \delta, \varepsilon, \zeta, \eta\} \ ((\exists e \in E \ e \leadsto_{\lambda} a) \implies (\exists e \in E \ e \leadsto_{\alpha} a)).$

Proof. Take arbitrary extension E and arbitrary $a \in Args \setminus E$. If $\lambda \neq \beta$ and $\exists e \in E \ e \leadsto_{\lambda} a$, then a = e from the definition of \leadsto_{λ} . But $e \notin Args \setminus E$. By contradiction, $\lambda = \beta$.

If m = 0 or T = 0, then $Args = \emptyset$, so the proof is trivial.

If m=1 and T=1, then by definition of $\leadsto_{\beta}, \leadsto_{\beta} = \emptyset$. So $\neg \exists e \in E \ e \leadsto_{\beta} a$. As the condition does not hold, $\exists e \in E \ e \leadsto_{\alpha} a$.

Otherwise, let $a = \langle i, j, t \rangle$. Because m > 2 or T > 2, then there exists i and t such that $\langle i, t \rangle \neq \langle i', t' \rangle$. By definition of \leadsto_{α} , $\langle i', j, t' \rangle \leadsto_{\alpha} a$.

Theorem 2 (Interval scheduling is stability-modellable). Let $\Lambda(S)$ iff $\forall \lambda \in \{\alpha, \beta, \gamma, \delta, \varepsilon, \zeta, \eta\}$ $\lambda(S)$. Λ is stability-modellable.

Proof.

- 1. \leadsto_{γ} conflict-models γ definition of \leadsto_{γ} , lemma 7 2. \leadsto_{δ} conflict-models δ definition of \leadsto_{δ} , lemma 7
- 3. \leadsto_{ε} conflict-models ε definition of $\leadsto_{\varepsilon},$ lemma 7
- 4. \leadsto_{ζ} conflict-models ζ definition of $\leadsto_{\zeta},$ lemma 7
- 5. \leadsto_{η} conflict-models η definition of $\leadsto_{\eta},$ lemma 7
- 6. $\left(\bigcup_{\lambda \in \{\alpha,\beta,\gamma,\delta,\varepsilon,\zeta,\eta\}} \leadsto_{\lambda}\right)$ stability-models Λ lemma 5, lemma 6, 1, 2, 3, 4, 5, lemma 8, theorem 1
- 7. Λ is stability-modellable 5
